This project analyzes Amazon customer survey data to understand purchasing behavior, satisfaction levels, and the impact of recommendations and reviews using descriptive analysis, segmentation, and market basket insights.

The dataset consists of approximately **800 survey responses** collected from Amazon customers. It contains customer demographic information, browsing and purchase behavior, satisfaction ratings, and feedback related to reviews and personalized recommendations.

Key Findings:

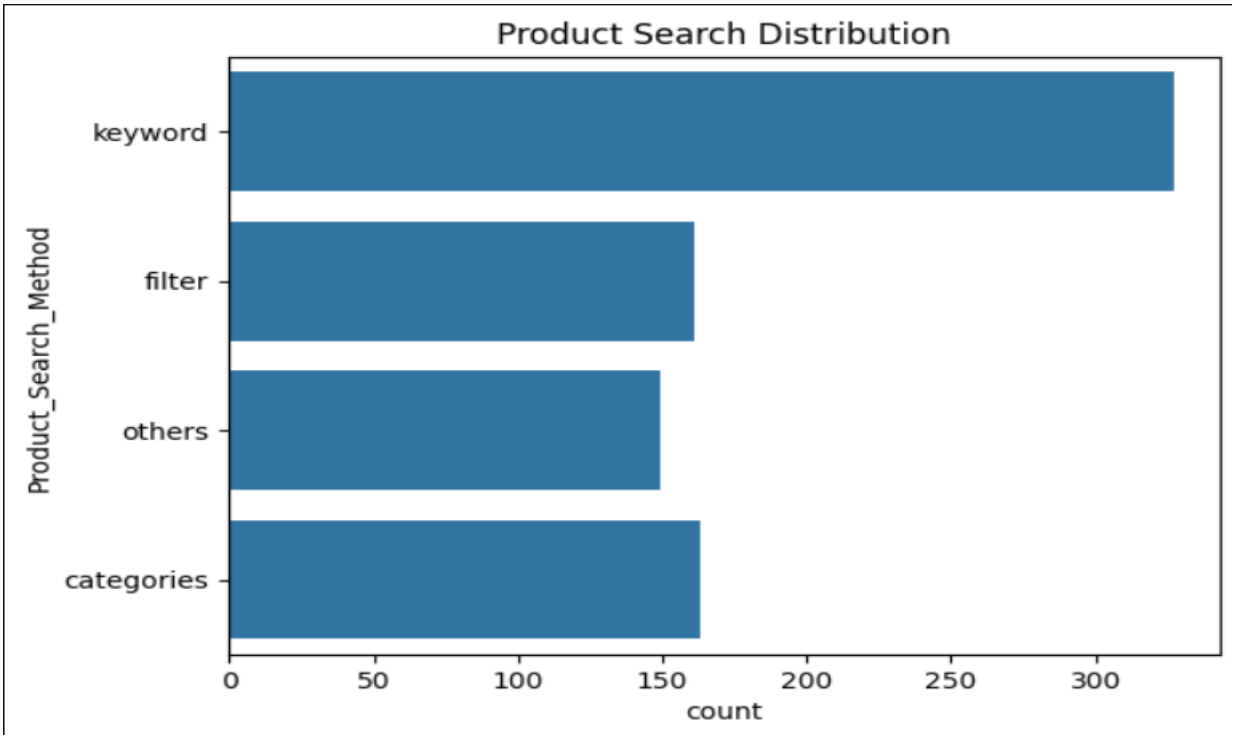

- Customer satisfaction is generally moderate, centered around a score of 3.
- Customers frequently purchase across multiple categories, especially Clothing and Fashion.
- Recommendation frequency shows weak correlation with satisfaction, indicating relevance matters more than quantity.
- Review reliability plays a stronger role in customer trust than recommendation exposure.
- Distinct customer segments were identified, including frequent buyers and at-risk customers.

Cart Abandonment Factors:

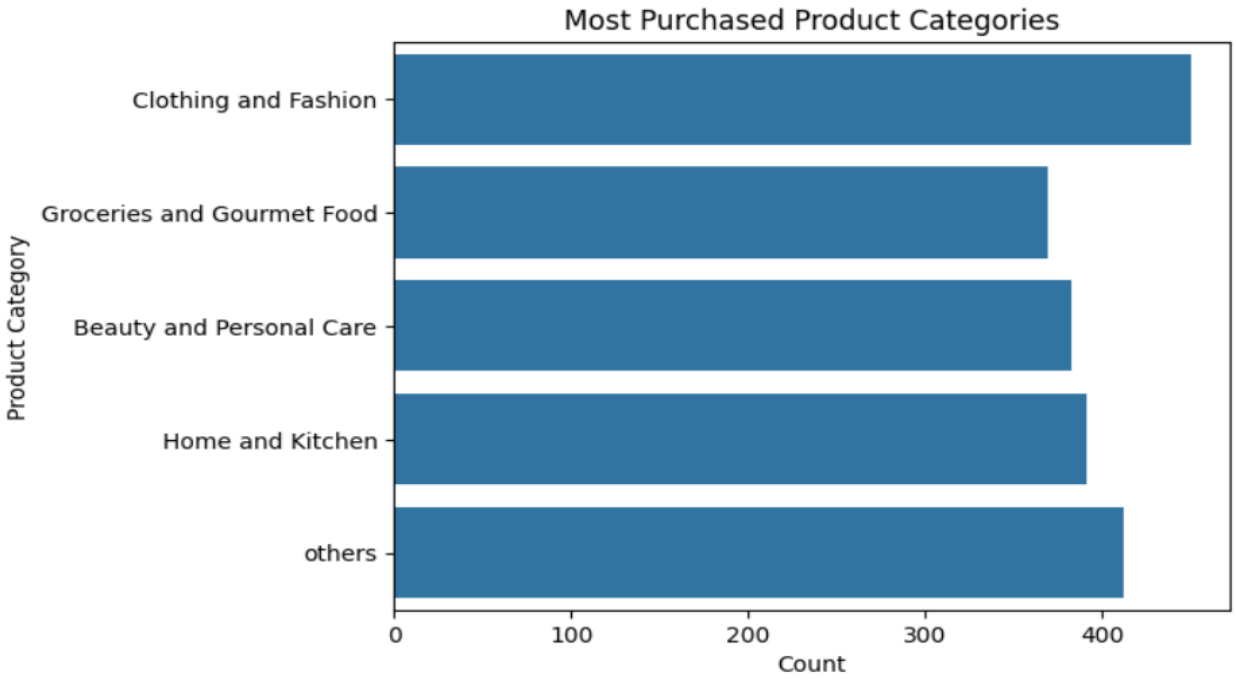

The primary reasons for cart abandonment are high shipping costs and better prices available elsewhere, highlighting strong price sensitivity among customers. Behavioral indecision also plays a significant role, suggesting opportunities to improve product information, pricing transparency, and checkout incentives.

Product Search Method:

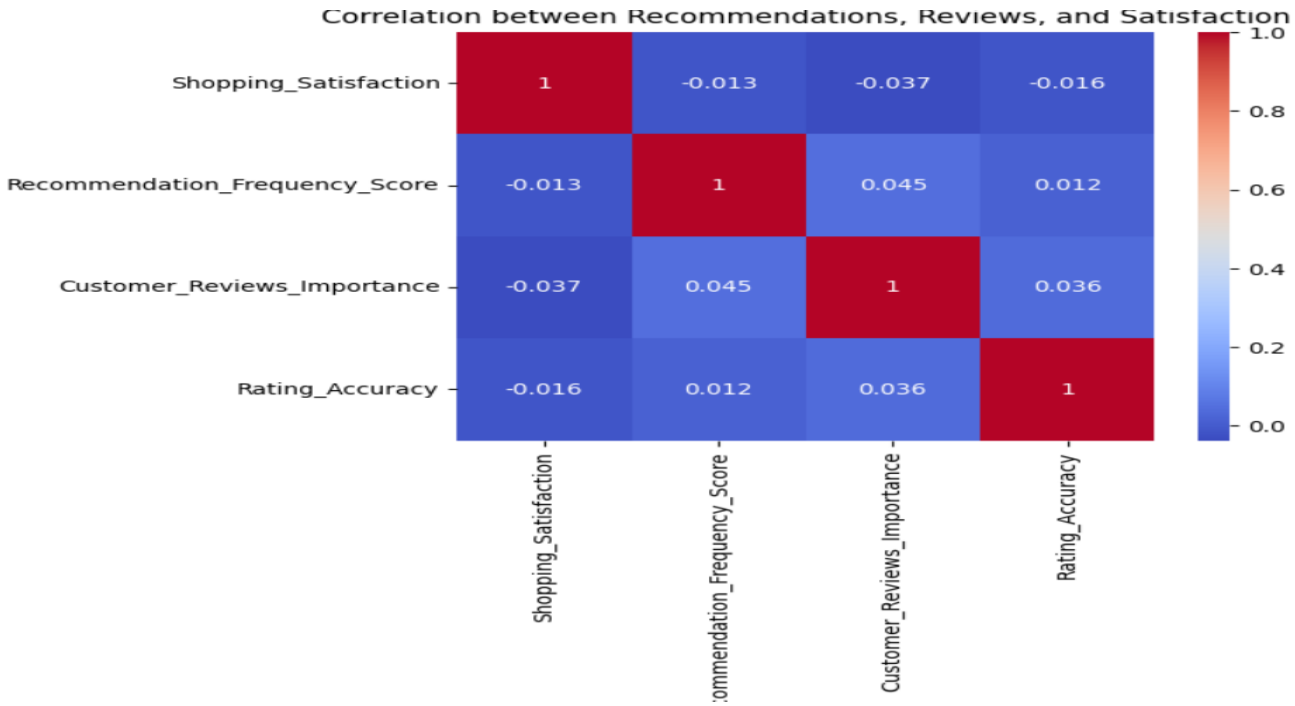

Keyword search is the most preferred product discovery method, followed by category browsing and filters. This suggests that customers use both direct search and exploratory browsing when shopping on Amazon.

Purchase Categories:

Customers frequently purchase across multiple categories, with Clothing and Fashion appearing most often, indicating strong cross-selling opportunities.

Correlation between Recommendation Usefulness and Satisfaction:

Correlations are generally negative to weak, indicating that recommendation quality and review trust does not influence customer satisfaction and that satisfaction is likely influenced by other factors such as pricing, delivery experience, and service quality.

Business Recommendation:

- Prioritize relevance and consistency in personalized recommendations.
- Strengthen review credibility to improve trust in ratings.
- Implement segment-based personalization strategies.
- Reduce cart abandonment by optimizing pricing and delivery experience.

Conclusion:

This analysis provides insights into Amazon customers' shopping behavior, satisfaction levels, and the impact of recommendations and reviews. The findings highlight that customer satisfaction is generally moderate and influenced more by experience quality and trust than recommendation frequency. These insights can help improve personalization strategies, enhance review credibility, and reduce cart abandonment through data-driven decisions.
